BBC Earth newsletterSign up to receive news, updates and exclusives from BBC Earth and related content from BBC Studios by email. Author: Molly Smith DipCNM, mBANT • Reviewer: Dimitrios Mytilinaios MD, PhD Last reviewed: October 28, 2021 Reading time: 5 minutes The cardiovascular system is a vital organ system which is quite literally at
the centre of everything. Comprised of the heart, blood vessels and the blood itself, it is divided into two loops which both begin in the heart and lungs for oxygenation, while the systemic circuit directs blood to the other tissues of the body. An intricate network of arteries,
veins and smaller blood vessels allow for these processes to occur. In this article, we're going to discover these major arteries and veins and help you to learn them with the help of diagrams and quizzes. Want to complete your cardiovascular knowledge? Check out our heart and blood quiz guides. Download our arteries and veins worksheet below
First of all, what are arteries and veins? Let's take a quick overview. Arteries transport blood away from the heart and towards the tissues. Possessing thick muscular walls and smaller as they move deeper into the
tissues, so that they can access all areas. Check out the video below to learn about the major arteries of the cardiovascular system. Veins do the opposite; they carry blood from the tissues and towards the heart. They contain thin walls and a larger lumen than arteries, since they hold blood at low pressure. Another feature of veins are valves which
prevent the blood from flowing backwards. Check out the video below to learn about the major veins of the cardiovascular system. Learning all of the major arteries and veins of the cardiovascular system. Learning all of the major arteries and veins of the cardiovascular system.
how we can revise them with the help of cardiovascular system diagram activities. Now that you're familiar with the major arteries and veins of the revision process (after watching a video tutorial, of course!) is labeling structures to
train our active recall abilities. Take a look at the cardiovascular system diagram below. As you can see, this diagram does not include all of the structures of the cardiovascular system, but you can test your knowledge of the veins and organs using our interactive
cardiovascular system quizzes further down the page. Arteries of the cardiovascular system diagram of the cardiovascular system, you can see labeled structures with what you've learned in the video. Once you think
you've got a solid idea, it's time to try our cardiovascular system labeling quiz. Here you'll be presented with a fill in the blank style diagram, in which you need to write the name of the cardiovascular system labeled and unlabeled
below. DOWNLOAD PDF WORKSHEET (BLANK)DOWNLOAD PDF WORKSHEET (LABELED) So you've watched a video, and taken our cardiovascular system labeling quiz. But have you really understood and memorized the topic? Could you still benefit from a bit more practice? If you answered "yes", look no further than our interactive
cardiovascular system quizzes. Covering not just major arteries and veins but also the organs and tissues of the cardiovascular system, these quizzes will truly prepare you for your exam. With several different quiz types available, you can test your knowledge from every angle. And if you want to learn a topic completely from scratch? These
circulatory system quizzes will help you do that too! Powered by a clever algorithm, they remember which questions you've answered wrong and give you more question bank quizzes or intelligent mix - a combination of all of the above. You can
even make a fully customized circulatory system quiz unique to your learning needs. Ready to get started? Start quizzes and labeled diagrams a useful anatomy learning method for you? Check out our free anatomy quiz
guides on several more topics! science that puts organisms into distinct groups to make their study easy and systematic. Modern scientific classification is based on structure and functions. Organisms with similar anatomical and morphological characteristics are placed in one group while those with different structures are grouped separately. Modern scientific classification is based on structure and functions.
biochemistry are used to give additional help in classifying organisms. There are seven major taxonomic groups. The kingdom is the largest group. Others are phylum (division for plants) class, order, family, genus and species, the smallest. Binomial Nomenclature Living organisms are named using Latin or Latinised names. Every organism has two
names. This double naming is called binomial nomenclature. This system of naming was devised by Carolus Linnaeus in the generic name of the generic name is the generic name of the generic name is the generic name of the generic name of the generic name is the name of the generic name is the generic name of the generic name of the generic name is the generic name of the generic name of the generic name of the generic name is the generic name of the generic name o
are written in italics or are underlined in manuscripts. Examples: Bean = Phaseolus vulgaris is specific name. Dog = Canis familiaris. Canis is the generic name, vulgaris is specific name. General Characteristics of Kingdoms Organisms are classified into five kingdoms. Monera, Protoctista, Fungi, Plantae
Animalia. Viruses do not fit neatly into any of the above kingdoms. They are simple and not cellular. They are metabolically inactive outside the host cell. Most of them can be crystallised like chemical molecules. Therefore they do not exhibit the characteristics of living organisms. Examples of Organisms in Each Kingdom and Their Economic
Importance Kingdom Monera General Characteristics Unicellular and microscopic Some single cells, others colonial Nuclear material not enclosed within nuclear membrane-prokaryotic Have cell wall but not of cellulose. Have few organelles which are not membrane bound Mitochondria absent Mostly heterotrophic, feeding saprotrophically or
parasitically, some are autotrophic. Reproduction mostly asexual through binary fission Most of them are anaerobes but others are aerobes Most move by flagella Examples include Escherichia coli, Vibrio cholerae and Clostridium tetani. Spherical known as Cocci. Rod shaped - e.g. Clostridium tetani Spiral shaped e.g. sprilla Coma shaped-Vibrios
e.g., Vibrio cholerae. Economic importance of bacteria Benefits to man include: They are used in food processing e.g., Lactobacillus used in processing of cheese, yoghurt. Involved in synthesis of vitamin Band K, in humans and breakdown of cellulose in herbivores. Genetic Engineering Bacteria are easily cultured and are being used for making
antibiotics, aminoacids and enzymes e.g. amylase, and invertase e.g., Escherichia coli. Nutrient cycling: Saprophytes They are involved in decomposition of dead organic matter. They are useful in the nitrogen cycle. Nitrogen fixing and nitrifying bacteria. They are useful in the nitrogen cycle. Nitrogen fixing and invertase e.g., Escherichia coli. Nutrient cycling: Saprophytes They are involved in decomposition of dead organic matter. They are useful in the nitrogen cycle. Nitrogen fixing and nitrifying bacteria.
oil spills in oceans and lakes. Harmful Effects Bacteria cause disease: To humans (e.g. Cholera). To animals (e.g. Anthrax). Bacteria cause food spoilage. Others cause food poisoning e.g. Salmonella. Denitrifying bacteria reduce soil fertility e.g., Pseudomonas denitrificans. Kingdom Protoctista Examples include; Algae such as spirogyra,
Chlamydomonas, euglena, Sargassum And protozoa such as amoeba, paramecium and Trypanosoma. General Characteristics They are said to be eukaryotic since their nucleus is bound by a membrane Most are mobile, and use flagella, cilia and pseudopodia. Some are sessile. They reproduce mainly asexually, by binary fission, fragmentation and
sporulation. Some reproduce sexually by conjugation. Some are heterotrophic e.g. spirogyra. Economic importance of protoctista Algae are the primary producers in aquatic food chains. They release a lot of oxygen to the atmosphere. Some cause human diseases like malaria and amoebic dysentry, sleeping
sickness Some are source of food for humans e.g. sargassum is a source of iodine Skeletons of diatoms used in paint making. Spirogyra: They have spiral chloroplast. They are green, thread-like filaments Chlamydomonas: This is a unicellular green algae and has a cup shaped chloroplast. They move towards light using the flagella Cilia assist the
organism to move. The shape is due to the presence of a thin flexible pellicle. Kingdom Fungi Multicellular fungi are made of thread-like structures called hyphae (singular hyphae) that form a mycelium. .e.g.Saccharomyces cereviseae(bread yeast). Others include Penicillium, Rhizopus, and edible mushroom Economic Importance of Fungi Beneficial
Effects Some fungi are used as food e.g. mushrooms. Some are decomposers which enhance decay to improve soil fertility - recycling of nutrients e.g., toadstools. Some are useful in production of antibiotics e.g., Penicillium griseofulvin. Used in
sewage treatment e.g., Fusarium spp. Harmful Effects Some cause food poisoning by producing toxic compounds e.g. Aspergillus flavus which produces aflatoxins. Some cause diseases to humans e.g., athlete's foot and ringworms. Others cause diseases to plants e.g., potato
blight (Irish potatoes) rust in tomatoes and smuts in cereals. Kingdom Plantae General Characteristics They are multicellular and eukaryotic. They are photosynthetic and have a pigment chlorophyll. Their cells have cellulose cell walls. They reproduce sexually, others asexually. Kingdom Plantae has three major divisions: Bryophyta, Pteridophyta
Spermatophyta. Division Bryophyta These include mosses and liverworts. Plant body is not differentiated into root, stem and leaves. They have rhizoids for absorbing water and anchoring the plant to substratum. Life cycle consists of two morphologically different plants, the gametophyte
and sporophyte. The two alternate. They show alternation of generations. The gamete producing gametophyte is attached to the gametophyte is attached to the gametophyte is attached to the gametophyte and is nutritionally dependent on it. They lack vascular system. Sexual reproduction is dependent on water. Division Pteridophyta: These include ferns and horsetails.
General Characteristics They have root and shoot system. Leaves are compound known as fronds, they have a vascular system. They show alternation of generations whereby the spore bearing sporophyte is the main plant. Spores are borne in clusters on the underside of leaves making sari. The gametophyte is an independent minute structure called
prothallus which is short lived. Sexual reproduction is dependent on water. Division Spermatophyta These are the seed bearing plants. General Characteristics Plant body is differentiated into root, stem and leaves. Vascular tissue consists of xylem and phloem. Sexual reproduction is independent of water. Male gametophyte (pollen grain) germinates
and grows to reach female gametophyte. They are divided into two sub-divisions: Gymnosperms Angiosperms. Gymnosperms Angiosperms are cone-bearing plants. Naked seeds. They are divided into two sub-divisions: Gymnosperms are cone-bearing plants. Naked seeds. They are divided into two sub-divisions: Gymnosperms are cone-bearing plants. Naked seeds. They are cone-bearing plants are 
Seeds are enclosed within a fruit. They comprise trees, shrubs and herbs. Xylem consists of vessels of tracheids. These are the most advanced plants. Angiosperms has two classes; Monocotyledonae Dicotyledonae Economic Importance of Spermatophyta They are a source of food for humans and
other animals. Source of fue1- wood fuel and charcoal. Source of timber for building and for paper. Ornamental plants. Useful in textile industry. Kingdom Animalia Most animals move from place to place in search of food. Major phyla are: Platyhelminthes (Tapeworm). Nematoda (Ascaris). Annelida (Earthworm). Mollusca (Snails). Arthropoda
chordata Phylum Arthropoda Distinguishing Characteristics They have jointed appendages, which are specialised for various functions. Their body is covered by a hardened exoskeleton made of chitin. It is shed at intervals to allow for growth. They have jointed body parts. Most are divided into head, thorax and abdomen. Some have two body parts,
General Characteristics Body is segmented. They have bilateral symmetry. Gaseous exchange is through tracheal system, book lungs or gills which opens to the outside through spiracles. Aquatic forms use gills. Reproduction is mainly sexual. They have an open circulatory system. Phylum Arthropoda divided into five classes; Crustacea, Arachnida,
Chilopoda, Diplopoda Insecta This division is based on: The number of limbs. Presence and number of body parts. Class Crustacea Most of them are aquatic, a few are terrestrial found in moist places e.g., woodlouse. Distinguishing Characteristics Two body parts head and thorax are fused to form cephalothorax and an abdomen
They have two pairs of antennae; one is small and branched, the other is long. They have five or more parts of limbs. Some of these are modified for other Characteristics Mouthparts include a pair of mandibles and two pairs
of maxillae. Gaseous exchange is through gills. They have a pair of compound eyes. Most crustaceans are free-living but a few are parasitic e.g., barnacles. Examples are cray-fish and crab. Class Arachnida Members are carnivorous and paralyse prey using poison produced from poison claws. Distinguishing Characteristics The body has two parts:
cephalothorax and abdomen. Cephalothorax is head fused to thorax. A pair of chelicerae, on ventral side of cephalothorax. They have no antennae. Instead they have no antennae. Instead they have a pair of short pedipalps which are sensitive to touch. Most arachnids use book lungs for gaseous exchange. Other characteristics include simple
eyes. Examples include garden spider, ticks, scorpions. Class Chilopoda e.g. Centipede Distinguishing Characteristics The body is elongate, and has 15 or more segments. Has a pair of legs on each segment. The body is dorso-ventrally flattened. Other characteristics include: Head has a pair of antennae.
Gaseous exchange through tracheal system. Are carnivorous. Class Diplopeda e.g. Millipede Distinguishing Characteristics Has two pairs of legs on each segment. They have a cylindrical body. Gaseous exchange is by tracheal system. Other characteristics: Head has
a pair of antennae. Are herbivorous. Class Insecta Distinguishing Characteristics Body is divided into three body parts head, thorax and abdomen. They breathe through spiracles, and gaseous exchange is through tracheal
system. The class is divided into several orders based on: Mouth parts - type e.g. biting or piercing. Position of mouthparts - ventral or anterior. Wings - presence or absence; number of wing types, structure, texture. Size of legs. Order Orthoptera Have biting and chewing mouthparts. Hind legs longer than other legs e.g. fore wings, leathery and
longer than hind legs . e.g. locusts and grasshoppers . Swarming - locusts are a menace to farmers and the environment as they destroy crops and vegetation. Order Diptera True flies e.g. houseflies, and mosquitoes have sucking and piercing mouthparts, 1 pair of wings. The second pair is vestigial- acts as balancer. Mouthparts are ventral. These are
disease vectors e.g., female anopheles mosquito transmits malaria. Order Lepidoptera Butterflies and moths have sucking mouthparts, two pairs of wings which are membranous. Some are
non-winged e.g. some ants. Bees are important in pollination i.e. in production of honey. Order Isoptera - Termites They have biting mouthparts which are anterior. Most are wingless, Those with wings they are membranous and of the same size. They are important in nutrient cycling as they feed on cellulose. Order Coleoptera - Beetles Have biting
mouthparts, Two pairs of wings, Fore wing hardened enclosing membranous wings. Destruction of stored grains and legumes (pulses) Phylum Chordata This name is derived from the term notochord exists only in embryonic
stages of development which in later stages is replaced by a vertebral column. Main Characteristics of Vertebrates Bees are important in pollination i.e. in production of honey Members of the phylum have a notochord in early stages of development. They have visceral clefts - which are slits perforating the body wall at the pharynx. In fish these slits
become gills while in higher chordates these slits are only present in embryo. They have a dorsal, hollow nerve cord. It develops into a brain at the anterior and spinal cord at the posterior end. The spinal cord at the posterior end spinal cord at the posterior end the body. They possess a
post-anal tail although rudimentary in some. They have a closed circulatory system. The heart is ventrally located. They possess an internal skeleton made of cartilage e.g. the shark. Others like Tilapia
have a bony skeleton. Distinguishing Characteristics They are aquatic. Movement is by means of fins. They have a streamlined body. They have a lateral line for sensitivity. Their heart has two chambers, the auricle and ventricle - simple circulatory system. Other Characteristics Their body temperature changes according to the temperature of the
environment. They are ectothermic (poikilothermic). Body covered with scales. They have gills for gaseous exchange. Exhibit external fertilisation. Class Amphibia Larval forms are aquatic while adults are terrestrial. Adults return to water for breeding e.g. frogs, toads, newts, salamanders. Distinguishing Characteristics Skin is soft and without scales
They have four well developed limbs. The hind limbs are longer and more muscular than forelimbs. The limb can be used for walking, jumping and swimming Gaseous exchange is through the skin, gills and lungs. Middle ear is present. Other Characteristics They have a three-chambered heart with two atria and one ventricle. Fertilisation is external.
They are ectothermic (poikilotherms). Class Reptilia Examples are snakes, crocodiles, lizards, chameleons, tortoises and turtles. Distinguishing Characteristics The skin is dry and is covered by horny scales. Fertilisation is internal. Some species eggs contain a lot of yolk and have either leathery or calcareous shells. They have a double circulatory
system. The heart has three chambers - two atria and a partly divided ventricle. However crocodiles have a four chamber heart. Other Characteristics They are ectothermic (poikilothermic). Have 2 pairs of limbs. They use lungs for gaseous exchange. Class Aves These are birds. They are terrestrial and arboreal and others are aquatic e.g. flamingo
goose, ostrich, penguin, hawk, dove. Distinguishing Characteristics Body is covered by feathers and legs with horny scales. They have two pairs of limbs. Fore limbs modified to form wings for flight. Hind limbs are for walking or swimming. The mouth is a protruding beak. They have hollow bones. They have double circulation with a four-chambered
heart (2 atria, 2 ventricles). They have lungs for gaseous exchange. Lungs are connected to air sacs in bones. Fertilisation is internal. They have constant body temperatures hence are homoiotherms (endothermic). Class Mammalia They are arboreal e.g. tree-squirrels, Others terrestrial e.g. humans Others
are aquatic e.g. dolphins and whales. Distinguishing Characteristics They have mammary glands hence name of the class. Body is covered with fur or hair. Their teeth are differentiated into four types (heterodont dentition). They have external ear-pinna. Most have sweat glands. They have external ear-pinna. Most have sweat glands hence name of the class. Body is covered with fur or hair.
abdominal. Other Characteristics Internal fertilisation - most give birth. They have a double circulatory system with a four-chambered heart. They are endothermic (homoiotherms) . Eg Duck-billed Platypus (egg-laying mammal) Eg.Kangaroo (pouched mammal) The young are born immature and are nourished in a pouch with milk from mammary
glands. Placental Mammals They give birth to fully developed young ones which are fed on milk from mammary glands. Some are aquatic. e.g. dolphins, whale, Others are flying e.g, bat; Most are terrestrial e.g. rabbits, elephants, buffalo, giraffe, antelope, cow, human being. Placental mammals are divided into various orders: Rodentia: e.g. rats, mice
- have one pair 9f upper incisors. Insectivora: e.g. mole-they are like rodents: Carnivora: e.g. dog; lion - flesh eaters, they have long pointed canines. Cetacea: e.g. whales and dolphins ¬Aquatic mammals. Forelimbs are flippers. Chiroptera: e.g. bats - Forelimbs form wings. Artiodactyla: e.g. antelopes, cattle - they are even toed with split hooves.
Perissodactyla: e.g. horse, donkey - they are odd toed with hooves. Proboscidea: e.g. elephant - upper lip and lower incisors. Have larger hind legs than forelegs. Primata: e.g. gorilla, orang utang, chimpanzee, monkeys - some are arboreal, with hand and foot for
grasping. Human - Homo sapiens - upright gait, opposable thumb hence use of tools. Construction and Use of Dichotomous Keys Biological keys are sets of statements that act as clues leading to the identification of an organism. By following the keys we can be able to place an organism in its group. The most common key is the dichotomous key. This
is a biological tool for identification of unknown organisms. The word dichotomous means branching into two. A single characteristic is considered at a time. Two contrasting statements are put forward to describe the characteristic is considered at a time. Two contrasting statements are put forward to describe the characteristic is considered at a time.
Construct a Dichotomous Key Use morphological characteristic as far as possible e.g., type of leaf. Use identical forms of words for two contrasting statements e.g.; a) Flowers scented. b) Flowers not scented. Start with a major characteristic that
divide the organisms into two large groups then proceed to lesser variations that would separate the organisms further into smaller groups. Use positive statements especially the first one. Avoid generalizations e.g. short plants. Be specific in your description e.g. a) plants above 1m tall. b) plants below 1m tall. Some Common Features Used for
Identification In Plants Leaves 1. Type of leaf arrangement on stem. The colour of leaf arrangement on stem. The colour of leaf arrangement on stem. The texture of leaf arrangement of leaf arrangement on stem. The texture of leaf arrangement of le
rectangular. Texture of stem smooth or spiny. Infloresence Are flowers terminal or lateral For each flower regular? Number of floral parts for each whorl. Are flower stem smooth or spiny. Infloresence Are flowers terminal or lateral For each flower regular? Number of floral parts for each whorl. Are flower regular? Number of floral parts for each whorl. Are flower regular? Number of floral parts for each whorl. Are flower regular? Number of floral parts for each whorl. Are flower regular? Number of floral parts for each whorl. Are flower regular? Number of flower regular r
of skeleton. Presence or absence of antennae. Body segmentation. Body covering: scales, fur, hair or feathers. Number of body parts. Locomotory structures: legs, wings and fins. Presence or absence of vertebral column. Presence and type of eves. Practical Activities To examine Bryophyta A mature moss plant is obtained. The specimen is observed
using a hand -lens. A labelled drawing showing structures is made: rhizoids, set a capsule, gametophyte, sporophyte .. To examine Pteridophyta A mature fern plant is observed using a hand lens. Sori can be seen on the lower side of fronds. A labelled drawing showing: frond, pinna, sorus, rhizome and adventitious roots. To examine
Spermatophyta A mature twig of either cypress or pinus with cones is obtained. Observation of Male and female is made using a hand-lens. The leaves are noted. The leaves show xerophytic characteristics e.g. they are rolled, or needle-like. A mature bean plant with pods is obtained, Observation of the leaves, stem and roots is made. Leaves are
sheath. They have a-fibrous root system. Floral parts are in threes. A maize gram has one cotyledon, Examination of Arthropoda Specimens are observed. The differences in the following
are noted: Body parts. Antennae. Other appendages. Eyes. Examination of Chordata The following specimen is placed into its class. Features each specimen is placed into its class.
environment. All organisms show interdependence on one another. Organisms are affected by their environment, and they in turn affect the environment. Green plants is mainly affected by environmental factors such as soil and climatic factors
On the other hand, organisms modify the environment through various activities. This interrelationship comprises the study of ecology. The study of ecology is important in several fields of study such as agriculture and environmental studies. Concepts and Terms Used in Ecology Habitat: This is the place or "home" that an organism lives or is found
e.g., forest or grassland. Niche: A niche is the functional unit in the habitat. It includes not only the specific place in which an organism lives but also how the organism functions. To avoid or reduce competition, organisms are separated by their niches, for example, different species of birds make their nest on one tree, some at tips of
terminal branches, and others feed on leaves, some on flowers and yet others on fruits of the same tree, i.e., food niche. Yet others feed on same food, e.g., worms in the same place but at different times - time niche. Population: The term population refers to the total number of individuals of a species living in a given area at a particular time. Density
is the number of individuals of a population found in a unit area, i.e., Dispersion: This is the distribution of individuals in the available space. Dispersion may be uniform as in human population in cities. Community: This is the term used to
describe all the organisms living together in an area. During the development of an ecosystem, the species composition of a community changes progressively through stages. Finally a steady state is reached and this is described as the climax community. This development of an ecosystem is termed succession. Each stage in development of an
ecosystem is a sere. Succession is primary when it starts in a previously inhabited area e.g. after clearing a forest. The Ecosystem: The community and the abiotic or non-living environment together make up an ecosystem or ecological system. In this system energy flow is clearly defined from producers
to consumers and nutrient cycling takes place in paths that links all the organisms and the non-living environment. Biomass: This is the maximum sustainable density in a given area e.g. the number of herbivores a given area can
support without overgrazing. Factors in an Ecosystem Abiotic factors (environmental factors) Temperature Is the hotness or coldness of an area or habitat. It directly affects the distribution and productivity (yield) of populations and animals
have adaptations that enable them to live in areas where temperatures are in the extremes such as the hot deserts and the cold polar regions. Temperature usually accelerates the rates of photosynthesis, transpiration, evaporation and the
decomposition and recycling of organic matter in the ecosystem. Light is required by green plants for photosynthesis. Light intensity, duration and quality affect organisms in one way or another. Atmospheric Pressure The force per unit area of atmospheric air that is exerted on organisms at different altitudes. Growth of plants and activity of
animals is affected by atmospheric pressure e.g., rate of transpiration in plants and breathing in animals. Salinity This describes the amount of moisture (water vapour) in the air. Humidity affects the rate of transpiration in plants
and evaporation in animals. pH Is the measure of acidity or alkalinity of soil solution or water. pH is very important to organisms living in water and soil. Most prefer a neutral pH. Wind: Is moving air currents also modify the temperatures
and humidity of the surroundings. Topography: These are surface features of a place. The topographical factors considered include altitudes, gradient (slope), depressions and hills. All these characteristics affect the distribution of organisms in an area e.g., the leeward and windward sides of a hill. Biotic factors: These are the living components in an
ecosystem, competition predation, symbiosis, parasitism, human activities. Inter-relationships Between Organisms in a particular habitat have different feeding levels referred to as trophic levels. There are two main trophic levels: Producers: These
organisms that occupy the first trophic level. They manufacture their own food hence are autotrophic. Consumers: These are herbivores and feed on organic substances manufactured by green plants. Secondary consumers: These are herbivores and feed on organic substances manufactured by green plants.
are carnivores and feed on flesh. First order carnivores feed on both plant and animal material. They can be primary, secondary or tertiary consumers. Competition: This describes the situation where two or more
organisms in the same habitat require or depend on the same resources. Organisms in an ecosystem compete for resource sike food, space, light, water and mineral nutrients. Competition takes place when the environmental resource is not adequate for all. Intraspecific competition. This is competition between organisms of the same species. For
example, maize plants in a field compete for water and nutrients among themselves. Interspecific competition. This refers to competition between organisms of different species, e.g., different species of predators can compete for water and prey among themselves. Predators can compete for water and prey among themselves. Interspecific competition.
prey). Saprophytism Saprophytism Saprophytism is the mode of nutrition common in certain species of fungi and bacteria. Such organisms feed on dead organic material and release nutrients through the process of decomposition or decay. Saprophytes produce enzymes, which digest the substrates externally. The simpler substances are then absorbed
Saprophytes help in reducing the accumulation of dead bodies of plants and animals. Harmful saprophytes cause rapid decay of foods such as fruits, vegetables, milk and meat. Others damage buildings by causing wood rot. Some fungi produce poisonous substances called aflatoxins. These substances are associated with cereal crops which are stored
under warm, moist conditions. If the infected grain is eaten, it may cause serious illness, and death. Parasitism This is an association between members of different species. The parasite lives on or in the body of another organism, the host. The parasite lives on or in the body of another organism, the host but the heist suffers harm as a result.
Symbiosis This is an association in which organisms of different species derive mutual benefit from one another. Some symbiotic associations are loose and the two partners gain very little from each other. Other symbiotic associations are loose and the two partners gain very little from each other. Some symbiotic associations are loose and the two partners gain very little from each other. Other symbiotic associations are loose and the two partners gain very little from each other.
of organisms on one another and the physical environment as nitrogen is traced from and back into the atmosphere Although nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is abundant in the atmosphere and the physical environment as nitrogen is a physical environmen
are referred to as nitrogen fixing bacteria convert ammonia into nitrites and nitrates. Denitrifying bacteria convert nitrogen fixing bacteria convert ammonia into nitrites and nitrates into atmospheric nitrogen. Energy Flow in an
Ecosystem Most of the energy used in an ecosystem is derived from the sun. Solar energy is trapped by photosynthetic plants. It flows through different trophic levels . At each level energy is lost as heat to space and also through different trophic levels. It flows through excretion and defecation. The amount of energy passed on as food from
one trophic level to another decreases progressively. The energy in the organisms is recycled back to plants through the various nutrient or material cycles. Food Chains A food chain is a linear relationship between producers and consumers. It represents the transfer of food energy from green plants through repeated stages of eating and being
eaten. Types of Food Chain Grazing food chain - starts with green plants. Detritus food chain - starts with dead organic material (debris or detritus). Detritivores feed on detritus. They include fungi, protozoa, insects, mites
annelids and nematodes. Examples of Food Chains Green plants ~ antelope -lion Algae ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ Tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Plant debris ~ bacteria -eprotozoa ~ mosquito larva Phytoplankron-eZooplankton ~ tilapia ~ kingfisher Phytoplankron-e
web. Several herbivores may feed on one plant. Similarly, a given herbivore may feed on different plants and fungi. These organisms feed on dead organic matter thereby causing decomposition and decay and releasing nutrients for plants. They form a link
between the biotic and the abiotic components. Pyramid of Numbers Refers to the number of organisms in each trophic level presented in a graphic form and a pyramid shape is obtained. This is because a herbivore feeds on many green plants. One
carnivore also feeds on many herbivores. In a forest the shape of the pyramid is not perfect. This is because very many small animals such as insects, rodents and birds feed on one tree. Pyramid of Biomass This is the mass of the producers and consumers at each trophic level drawn graphically. Population Estimation Methods It is important to find or
estimate the sizes of the different populations in a habitat. Direct counting or head count which involves the counting of every individual, is not always applicable for all organisms . e.g., it is impossible to count directly the numbers of grasshoppers in an area. Different sampling methods are thus used. A sample acts as a representative of the whole
population. . Sampling Methods Quadrat Method A Quadrat is a square, made of woos metal/hard plastic. It can also be established on the ground using pegs, rope/permanent coloured ink, using metre rule or measuring tape. The size is usually one square metre (1M2), in grassland. In wooded or forest habitat it is usually larger, and can reach upto
20 m2 depending on particular species under investigation. The number of each species found within the quadrat is counted and recorded. Total number of quadrats and their positions is determined by the type of
vegetation studied. In a grassland, the quadrat frame can be thrown at random. In other habitats of forest, random numbers that determine the locus at which to establish a quadrat are used. Line Transect A line transect is a string or rope that is stretched along across the area in which all the plants that are touched are counted. It is tied on to a pole
or tent peg. It is particularly useful where there is change of populations traversing through the habitat to be studied. This method can also be used in studying the changes in growth patterns in plants over a period of time. Belt Transect Two line transects are set parallel to each other to enclose a strip through the habitat to be studied.
rodents, arthropods and birds. The animals are caught, marked, counted and released. For example, grasshoppers can be caught with a net and marked using permanent ink. After sometime, the same area is sampled again, i.e., the grasshoppers can be caught with a net and marked using permanent ink. After sometime, the same area is sampled again, i.e., the grasshoppers can be caught with a net and marked using permanent ink.
ones is also recorded: Let the number caught and marked be a. The total number of grasshoppers in the second catch be b. The number of grasshoppers in the second catch be c. The total number of marked ones in the second catch be b. The number of grasshoppers in the area be T. The total number of marked ones in the second catch be c. The total number of marked ones in the second catch be c. The total number of grasshoppers in the second catch be c. The total number of grasshoppers in the second catch be c. no movement in and out of the study area. There is even distribution of the organisms in the study area. There is random distribution of the following population characteristics: Density: Density is calculated by
dividing the number of organisms by the size of the area studied. Frequency: Frequency is the number of times that a species occurs in the area covered by a particular species. For example, a given plant species may cover the whole. of a given area. In this case the plant is said to
have 100% cover. Dominance: This is the term used to describe a species that exerts the most effect on others. The dominance may be in terms of high frequency or high density. Adaptations of Plants to Various Habitats. Plants found
beneath the canopies of trees are adapted to low light intensities by having broad leaves. Xerophytes These are plants that grow in dry habitats, i.e., in deserts and semi-deserts are adaptations to reduce the rate of transpiration in order to save on water consumption. Others have water storage structures. Adaptations include: Reduction of leaf
surface area by having needle-like leaves, rolling up of leaves and shedding of leaves during drought to reduce water holes. Few, small stomata, creating spaces with humid still air to reduce water holes. Few, small stomata,
on lower epidermis to reduce water loss. Stomata open at night (reversed stomatal rhythm) to reduce water loss. Deep and extensive root systems for absorption of water. Development of flattened shoots and succulent tissue for water loss. They
have no special adaptations. Stomata are found on both upper and lower leaf surfaces for efficient gaseous exchange and transpiration. However, those found in constantly wet places e.g. tropical rain forests, have features that increase transpiration. These plants are called hygrophytes. The leaves are broad to increase surface areas for transpiration
and thin to ensure short distance for carbon (IV) oxide to reach photosynthetic cells and for light penetration. They have grandular hairs or byhathodes that expel water into the saturated atmosphere. This phenomenon is called guttation. Hydrophytes (Water plants)
Water plants are either submerged, emergent or floating. Submerged Plants The leaves have an epidermis with very thin walls and a delicate cuticle. They have no stomata. Water is excreted from special glands and pores at the tips. Other adaptations include the following: Presence of large air spaces and canals (aerenchyma) for gaseous exchange
and buoyancy. Some plants have filamentous leaves In order to increase the surface area for absorption of light, gases and mineral salts. Some plants are rootless, hence support provided by water. Mineral salts and water absorbed by all plant surfaces. In some plants, the stem and leaves are covered with a waxy substance to reduce absorption of
water. e.g. Ceratophyllum and Elodea sp. Floating Plants Their structure is similar to that of mesophytes. The leaves are broad to increase the surface to increase the surface area for water loss. Examples are Pistia sp. (water lettuce), Salvinia and Nymphea. Halophytes
(Salt plants) These are plants that grow in salt marshes and on coastlines. They have root cells that concentrate salts and enable them to take in water by osmosis. They have shiny leaves to reduce water loss. The mangrove
plants have roots that spread horizontally, and send some branches into the air. These aerial roots are known as breathing roots or pneumatophores. They have lenticel-like openings called pneumatothodes through which gaseous exchange takes place. Pollution Effect of Pollution on Human Beings and other Organisms Pollution This is the
introduction of foreign material, poisonous compounds and excess nutrients or energy to the environment in harmful proportions. Any such substance is called a pollutant. Effects and Control of causes of Pollutants in Air, Water and Soil Industrialisation are the main causes of pollutant. Effects and Control of causes of Pollutants in Air, Water and Soil Industrialisation are the main causes of pollutants.
delicate balance in the biosphere gets disturbed. The disturbance leads to the creation of conditions that are un-favourable to humans and other organisms. Sources of Pollutants Motor vehicles release carbon (II) oxide, sulphur (IV) oxide, and nitrogen oxides and hydrocarbons. Agricultural chemicals, fertilisers and pesticides. Factories
manufacturing and metal processing industries. They release toxic substances and gases as well as synthetic compounds that are bio-¬undegradable. They release toxic substances e.g. arsenic, beryllium, lead and cadmium. Radioactive waste: Leakages from nuclear power stations and testing sites release radioactive waste.
elements like strontium-90 which can eventually reach man through the food chain. Domestic waste and sewage are released raw into water bodies. Oil spills from accidents in the seas and leakage of oil tankers as well as from offshore drilling and storage and processing. Water Pollution. In most cases, chex, pical wastes from industries are
discharged into water. Toxic chemicals such as mercury compounds may be ingested by organisms. Insecticides like DDT, and weed—killers eventually get into the water and contaminate it. Oil and detergents also pollute water. Excess nitrates and phosphates from sewage and fertilisers cause overgrowth of algae and bacteria in water. This is called
eutrophication. As a result there is insufficient oxygen which causes the deaths of animals in the water. Air pollution: Smoke from industries and motor vehicles contains poisonous chemicals like carbon (IV) oxide and oxides of nitrogen. When sulphur (IV) oxide and oxides of nitrogen dissolve in rain, they fall as
acid rain. Accumulation of carbon (IV) oxide in the atmosphere causes the infrared light to be confined within the atmosphere, the earth's temperature rises. This is called the greenhouse effect. Carbon particles in smoke coat the leaves of plants and hinder gaseous exchange and photosynthesis. The particles also form smog in the air. Lead
compounds are from vehicle exhaust pipes. All these have negative effects on man and the environment. Soil/Land pollution: Plastics and other man-made materials are biologically non-degradable i.e they are not acted upon by micro-organisms. Scrap metal and slag from mines also pollute land. Failure to rehabilitate mines and quarries also pollute.
land. Effects of Pollutants to Humans and other organisms Chemical pollutants e.g. nitrogen oxides, fluorides, mercury and lead cause physiological and metabolic disorders to humans and domestic animals. Some hydrocarbons as well as radioactive pollutants to Humans and other organisms Chemical pollutants e.g. nitrogen oxides, fluorides, mercury and lead cause physiological and metabolic disorders to humans and other organisms Chemical pollutants e.g. nitrogen oxides, fluorides, mercury and lead cause physiological and metabolic disorders to humans and other organisms.
ecosystems. Birds that eat fish die due to inability to fly as feathers get covered by oil. Molluscs and crustaceans on rocky shores also die. Control of Air Pollution Use of lead-free petrol and low sulphur diesel in vehicles. Use of smokeless fuels e.g electricity or solar. Filtration of waste gases to remove harmful gases. Liquid dissolution of waste gases
In Kenya, factories are subjected to thorough audits to ensure that they do not pollute the environment. Factories should be erected far away from residential areas. Reduce volume or intensity of sound. Use of ear muffs. Vehicle exhaust systems should be erected far away from residential areas. Reduce volume or intensity of sound. Use of ear muffs.
fuel. Water Pollution Treatment of sewage. Treatment of sewage. Treatment of industrial waste before discharge into water. Use of controlled amounts of agrochemicals into water management. Stiff penalties for oil spillage. Use of Pseudomonas bacteria that naturally feed on oil
and break it up. Soil Pollution Addition of lime to farms to counteract the effect of agrochemicals. Recycling of solid waste. Use of biodegradable materials and chemicals and chemicals and chemicals. Good soil management to avoid soil erosion. Human Diseases The term disease denotes any condition or disorder that disrupts the
steady state of well being of the body. Health is a state of physical, mental and emotional well being in the internal environment of the body. Some of the causes of diseases are due to entry of pathogens and parasites. Pathogens include bacteria, viruses, protozoa and fungi. Parasites are organisms which live on or in the body of another organisms
toxin, enterotoxin, that causes inflammation of the wall of the intestine leading to: Severe diarrhoea that leads to excessive water loss from body. Abdominal pain Vomiting Dehydration which may lead to death. Prevention and Control Adequate sanitation such as water purification sewage treatment and proper disposal of human faeces. Public and
personal hygiene e.g washing hands before meals and washing fruits and vegetables, boiling drinking water. Vaccination Carriers should be identified, isolated and treated during outbreaks. Treatment Use of appropriate antibiotics. Correcting fluid loss by injecting fluids or by administration of oral rehydration solutions. Typhoid Causative agent The
disease is caused by Salmonella typhi. Transmission is through contaminated water and food. It is also transmitted by certain 'e.g foods, e.g. oysters, mussels and shell fish. Symptoms Fever Muscle pains Headache Spots on the trunk of the body Diarrhoea In severe cases mental confusion may result and death. Prevention Boil drinking water. Proper
sewage treatnient. Proper disposal of faeces, if not flushed use deep pit latrines. Observe personal hygiene e.g. washing fruits and vegetables. Treatment Use of appropriate antibiotics. Protozoa Malaria is caused by the protozoan plasmodium. The most common species of plasmodium are P. falciparum, P. vivax
P. rnalariae and P. ovale with varying degree of severity. Transmission Is by female anopheles mosquito as it gets a blood meal. Symptoms Headache, sweating, shivering, high temperature (40-41 0C) chills and joint pains. The abdomen becomes tender due to destruction of red blood cells by the parasites. Prevention Destroy breeding grounds for
mosquitoes by clearing bushes and draining stagnant water. Kill mosquito larvae by spraying water surfaces with oil. Use insecticides to kill adult mosquitoes Sleeping under a mosquito net. Take preventive drugs. Treatment Use appropriate anti-malarial drugs. Amoebic dysentry (Amoebiasis) Cause This disease is caused by Entamoeba histolytica
The parasites live in the intestinal tract but may occasionally spread to the liver. Transmission They are transmitted through contaminated water and diarrhoea. Prevention and control Proper disposal of
human faeces. Boiling water before drinking. Personal hygiene e.g. washing hands before meals. Washing vegetables and fruits before eating. Treatment of infected people with appropriate drugs. Parasitic Diseases Ascaris lumbricoides lives in the intestines of a man or pig, feeding on
the digested food of the host. The body of the worm is tapered at both ends. The female is longer than the male. Mode of transmission The host eats food contaminated with the eggs, the embryo worms hatch out in the intestine. They are carried in the bloodstream to the heart and
then into the lungs. As they travel through the bloodstream, they grow in size. After sometime, the worms are coughed out from the air passages and into the oesophagus. They are then swallowed, eventually finding their way into the intestines where they grow into mature worms. Effects of Ascaris lumbricoides on the host The parasites feed on the
host's digested food. This results in malnutrition especially in children. If the worms are too many, they may block the intestine and interfere with digestion. The worms sometimes wander along the alimentary canal and may pass through the nose or mouth. In this way, they interfere with breathing and may cause serious illness. The larvae may cause
severe internal bleeding as they penetrate the wall of the intestine. Adaptive Characteristics The female lays as many as 25 million eggs. This ensures the continuation of the species. Eggs are covered by a protective cuticle that prevents them from dehydration. The adult worms tolerate low oxygen concentration. Have mouth parts for sucking food
and other fluids in the intestines. Has a thick cuticle or pellicle to protect it from digestive enzymes produced by the host. Control and Prevention Personal hygiene e.g. washing of fruits and vegetables. Treatment Deworm using appropriate drugs ¬ant-helmintics. Schistosoma Schistosoma or
bilharzia worm is a flat worm, parasitic on human beings and fresh water snails. (Biomphalaria and Bulinus.) The snail act as intermediate host. Mode of Transmission Schistosoma haematobium ¬infects the urinary system mainly the bladder S.
japonicum and S. mansoni both infect the intestines. Schistosoma haemotobium is common in East Africa where irrigation is practised and where slow moving fresh water streams harbour snails. It is spread through contamination of water by faeces and urine from infected persons. The embryo (miracidium) that hatch in water penetrates into snails
of the species Biompharahia and Bulinus. Inside the snail's body, the miracidium undergoes development and multiple fission to produce rediae are released into the water. The cercariae which infect human through the skin
and enters blood vessel. Effects on the host Inflammation of tissues where egg lodge. Ulceration where eggs calcify, Egg block small arteries in lungs leading to less aeration of blood. The body turns blue - a condition known as cyanosis. If eggs lodge in heart or brain, lesions formed can lead to death. Bleeding occurs as the worms burrow into blood
vessels (faeces or urine has blood). Pain and difficulty in passing out urine. Nausea and vomiting. When eggs lodge in liver ulceration results in liver cirrhosis. Death eventually occurs. Adaptive Characteristics The female has a thin body and fits into small blood vessel into intestine lumen. Many
eggs are laid to ensure the survival of the parasite. Large numbers of cercariae are released by snail. The miracidia and cercariae larvae have glands that secrete lytic enzymes which soften the tissue to allow for penetration into host. The male has a gynecophoric canal that carries the female to ensure that eggs are fertilised before being shed. Has
suckers for attachment. Prevention and Control Drain all stagnant water Boil drinking water. Do not wade bare feet in water Boil drinking water boots and gloves (for those who work in rice fields). Eliminate snails, by spraying with molluscides. Reporting to doctor early when symptoms appear for early treatment. Practical Activities Ecology is best
studied outdoors. Students identify a habitat within or near the school compound, e.g. a flower bed. The quadrat method is used. Observation and recording of the various animals as well as their feeding habits is done. Birds that feed on the plants or arthropods in the area studied are noted through observation of habitat at various times of the day.
Food chains are constructed e.g green plants ~ caterpillar ~ lizard and many others involving all organisms in the area. The number of plants is easily counted and recorded and ratio of consumers to producers calculated. It will be noted that in
terms of numbers where invertebrates are involved, there are very many consumers of one plant. Several other quadrats are established and studied and averages calculated. Adaptions to Habitat Hydrophytes e.g water lily is observed. Students should note the poorly developed root systems and broad leaves. Stomata
distribution on leaf surface is studied through microscopy or by emersing a leaf in hot water and counting number of bubbles evolved. Mesophytes Ordinary plants e.g bean hibiscus and zebrina can be studied. Size of leaves is noted and stomata distribution studied. Size of leaves is noted and stomata distribution studied.
The root system e.g in sisal is noted as shallow but extensive. It will be noted that sisal has fleshy leaves and Euphorbia have fleshy stem but leaves are reduced to small hair-like structures. Comparison of Root nodules from fertile and poor soils Root nodules Are swellings on roots of leguminous plants. Soil fertility determines
number of root nodules per plant. Bean plants are best used in this study. One plot can be manured while the other is not. Similar seeds are planted in the two plots. The number of nodules per plant is counted. An average for each plot is
calculated. It is noted that the beans from fertile soil have more and large nodules than those grown in poor soils. Estimation of Population using Sampling Methods The number of organisms both producers and the various consumers is recorded in each area studied e.g. using a quadrat. The total area of the habitat studied is measured. The average
number of organisms per quadrat (1 m2) is calculated after establishing as many quadrats as are necessary to cover the area adequately. Total population of organisms is calculated from the area sampled. Air temperature soil surface temperature are taken and recorded. This is best done at different
times of day, i.e., morning afternoon and evening. Any variations are noted. pH of the soil is measured using pH distilled water to make a solution. Litmus papers can be used to indicate if soil is measured using anhydrous blue cobalt chloride paper which gives a mere
indication of level of humidity. A windsock is used to give an indication of direction of wind. As all the abiotic factors are recorded observations are made to find the relationships between behaviour of animals. The direction of wind will affect growth of
plants. The level of humidity determines the type, number and distribution of organisms in an area. Reproduction is a characteristic of all living organisms and prevents extinction of a species. There are two types of
reproduction: sexual and asexual reproduction involves the fusion of male and female gametes to form a zygote. Asexual reproduction does not involve gametes. Cell Division Sexual reproduction involves the fusion of male and female gametes to form a zygote. Asexual reproduction does not involve gametes. Cell Division Sexual reproduction does not involve gametes.
homologous chromosomes. Each chromosomes. Each chromosomes contains a specific number of cells in each organism. The cells in each organism to bring about increase in number of cells, resulting in growth and repair.
The number of chromosomes in daughter cell. Meiosis This type of cell division takes place in reproductive organs (gonads) to produce gametes. The number of chromosomes in the gamete is half that in the mother cell. Mitosis Mitosis is divided into four main stages. Prophase, Metaphase, Anaphase and
Telophase. These stages of cell division occur in a smooth and continuous pattern. Interphase is used to describe the state of the nucleus when the cell is just about to divide. During this time the following take place: Replication of genetic material so that daughter cells will have the same number of chromosomes as the parent
cell. Division of cell organelles such as mitochondria, ribosomes and centrioles, Energy for cell division is synthesised and stored in form of Adenosine Triphosphate (ATP) to drive the cell through the entire process. During, interphase, the following observations can be made: Chromosomes are seen as long, thin, coiled thread-like structures, Nuclear
membrane and nucleolus are intact. Prophase The chromosomes shorten and thicken. Each chromosome is seen to consist of a pair of chromatids joined at a point called centromere. Centrioles (in animal cells) separate and move to opposite poles of the cell. The centre of the nucleus is referred to as the equator. Spindle fibres begin to form, and
connect the centriole pairs to the opposite poles. The nucleolus and nuclear membrane disintegrate and disappear. Metaphase Spindle fibres by the centromeres. Chromatids begin to separate at the
centromere. Anaphase Chromatids separate and migrate to the opposite poles due to the shortening of spindle fibres. Chromatids becomes a chromosome. In animal cells, it is due to deposition of
cellulose along the equator of the cell. (Cell plate formation). A nuclear membrane forms around each set of chromosome later become less distinct. Significance of Mitosis It brings about the growth of an organism: It brings about asexual reproduction. Ensures that the chromosome number is retained. Ensures that the chromosome later become less distinct.
constitution of the offspring is the same as the parents. Meiosis Meiosis involves two divisions of the parental cell resulting into four daughter cells. The mother cell had. In the first meiotic division there is a reduction
in the chromosome number because homologous chromosomes and not chromatids separate. Each division has four stages Prophase, Metaphase, Anaphase and Telophase and build up of energy to be used during the meiotic division. First
Meiotic division Prophase I Homologous chromosomes lie side by side in the process of synapsis forming pairs called bivalents. Chromosomes may become coiled around each other and thicken hence become more visible. Chromosomes shorten and thicken hence become more visible.
over at the chiasmata exchanging chromatid portions. Important genetic changes usually result. Metaphase I Spindle fibres are fully formed and attached to the centromeres. The bivalents move to the equator of the spindles. Anaphase I Homologous chromosomes separate and migrate to opposite poles. This is brought about by shortening of spindle
fibres hence pulling the chromosomes. The number of chromosomes at each pole is half the number in the mother cells. Second Meiotic Division Usually the two daughter cells go into a short resting stage (interphase) but sometimes the chromosomes remain condensed and the
daughter cells go straight into metaphase of second meiotic division. The second meiotic division takes place just like mitosis. Prophase II Spindle forms and are attached to the chromatids at the centromeres. Chromatids move to the equator. Anaphase II Sister chromatids separate from
each other Then move to opposite poles, pulled by the shortening of the spindle apparatus disappears. The nucleolus reappears and nuclear membrane is formed around each set of chromatids. The chromatids become chromosomes. Cytoplasm divides and four daughter cells are formed. Each has a haploid number of
chromosomes. Significance of Meiosis Meiosis brings about formation of gametes that contain half the number of chromosomes as the parent cells. It helps to restore the diploid chromosomes as the parent cells. It helps to restore the diploid chromosomes as the parent cells. It helps to restore the diploid chromosomes as the parent cells. It helps to restore the diploid chromosomes as the parent cells.
reproduction is the formation of offspring from a single parent. The offspring are identical to the parent. Types of asexual reproduction. Binary fission in amoeba. Spore formation in Rhizopus. Budding in yeast. Binary fission the parent organism into two daughter cells. The nucleus first divides into two and then the
cytoplasm separates into two portions Binary fission also occurs in bacteria, Paramecium, Trypanosoma and Euglena. Spore formation in Rhizopus Rhizopus is a saprophytic fungus which grows on various substrate such as bread, rotting fruits or other decaying organic matter. The vegetative body is called mycelium which has many branched threads
called hyphae. Horizontal hyphae are called stolons. Vertical hyphae are called sporangiophore become swollen to form sporangium contains many spores. As it matures and ripens, it turns black in colour. When fully mature the sporangium wall burst and release spores which
are dispersed by wind or insects. When spores land on moist substratum, they germinate and grow into a new Rhizopus and start another generation. Spore formation in ferns The fern plant is called a sporophyte. On the lower side of the mature leaves are sari (Singular: sorus) which bear spores. Budding in Yeast Budding involves the formation of a
protrusion called a bud from the body of the organism. The bud separates from the parent cell, in yeast budding goes on so fast and the first bud starts to form another bud before the separation. A short chain or mass of cells is formed. Sexual Reproduction in Plants In flowering plants, the flower is the reproductive organ which is a specialised shoot
consisting of a modified stem and leaves. The stem-like part is the pedicel and receptacle, while modified leaves form corolla and calyx. Structure of a flower when it is in a bud. Some flowers have an outer whorl made of sepal-like structures
called epicalyx. Corolla consists of petals. The petals are brightly coloured in insect - pollinated flowers. Androecium Is the flower. It consists of a filament whose end has an anther. Inside the anther are pollen sacs which contain pollen grains. Gynoecium (pistil) Is the female part of the flower. It
consists of one or more carpels. Each carpel consists of an ovary, a style and a stigma. The ovary contains ovules which become seeds after fertilisation. A monocarpous pistil has one carpel e.g. beans. A polycarpous pistil has one carpel e.g. beans. A polycarpous pistil has many carpels.
syncarpous as in Hibiscus. A complete flower has all the four floral parts. A regular flower can be divided into two halves by any vertical section passing through the centre. e.g. morning glory. Irregular flower can be divided into two halves by any vertical section passing through the centre. e.g. morning glory. Irregular flower can be divided into two halves in only one plane e.g. crotalaria. Pollination This is the transfer of pollen grains from the anther to the stigma.
Types of pollination Self pollination is the transfer of pollen grains from the anther of one flower to the stigma of a different flower, of the same species. Agents of pollination include wind, insects, birds and mammals.
Insect pollinators include bees, butterflies and mosquitoes. Mechanisms that hinder self-pollination Stamens ripen early and release their pollen grains before the anthers release the pollen grains. This is called protogyny and is common in
grasses. Self sterility or incompatibility Pollen grain are sterile to the stigma of the same flower, e.g. in maize flower. Shorter stamens than pistils. Fertilisation in Plants The pollen grain contains the generative nucleus and a tube nucleus. When the pollen grain lands on the stigma, it absorbs nutrient and germinates forming a pollen tube. This pollen
tube grows through the style pushing its way between the cells. It gets nourishment from these cells. The pollen tube nucleus follows behind the tube nucleus form two male gamete nuclei. The pollen tube enters the ovule through the micropyle. When the
```

pollen tube penetrates the ovule disintegrates and the pollen tube bursts open leaving a clear way for the male nucleus fuses with the egg cell nucleus to form a diploid zygote which forms the primary endosperm.

```
This is called double fertilisation. After fertilisation. After fertilisation the following changes take place in a flower: The integuments develops into an embryo. The triploid nucleus develops into a fruit. The ovary wall develops into pericarp. The style, dries up
 and falls off leaving a scar. The corolla, calyx and stamens dry up and fall off. In some the calyx persists. Fruit formation Fruits development without fertilisation of fruits False fruits develops from other parts such as calyx, corolla and receptacle, e.g.
apple and pineapple which develops from an inflorescence. True fruits develop from the ovary, e.g. bean fruit (pod). True fruits can be divided into Dehiscent which split open to release seeds and indehiscent which do not open. Types of fruits Placentation
This is the arrangement of the ovules in an ovary. Marginal placentation: The placenta is on the ridges on ovary wall. Ovules are in them e.g. pawpaw. Axile placentation: The placenta is on the ridges on ovary wall. Ovules are in them e.g. pawpaw. Axile placentation: The placenta is on the ridges on ovary wall. Ovules are in them e.g. pawpaw.
 placentation. The placenta is formed at the base of the ovary e.g. sunflower. Free Central placentation. Placenta is in the centre of the ovary. There are no loculi e.g. in primrose. Methods of fruit and seed dispersal Animal dispersal Fleshy fruits are eaten by animals. Animals are attracted to the fruits by the bright colour, scent or the fact that it is
 edible. The seeds pass through the digestive tract undamaged and are passed out with faeces. E.g. tomatoes and guavas. Such seeds have hard, resistant seed coats. Others have fruits with hooks or spines that stick on animal fur or on clothes. Later the seeds are brushed of or fall off on their own e.g. Bidens pilosa (Black jack). Wind dispersal Fruits
 and seeds are small and light in order to be carried by air currents. A fruit that is a capsule e.g. tobacco split or has pores at the top e.g. Mexican poppy. The capsule is attached to along stalk when swayed by wind the seeds are released and scattered. Some seeds have hairy or feather-like structures which increase their surface area so that they can
be blown off by the wind e.g. Sonchus. Others have wing-like structures e.g. Jacaranda and Nandi Flame. These extensions increase the surface area of fruits and seeds such that they are carried by the wind. Water dispersal Fruits like coconut have fibrous mescocarp which is spongy to trap air, the trapped air make the fruit light and buoyant to float
on water. Plants like water lily produce seeds whose seed coats trap air bubbles. The air bubbles make the seeds float on water and are carried away. The pericarp and seed coats trap air bubbles make the seeds float on water and are carried away. The pericarp and seed coats trap air bubbles make the seeds float on water and are carried away. The pericarp and seed coats trap air bubbles make the seeds float on water and are carried away. The pericarp and seed coats are waterproof. Self dispersal (explosive) Mechanism This is seen in pods like bean and pea.
away from parent plant. Reproduction in Animals Sexual reproduction involves the fusion of gametes. In animals two individuals are involved, a male and a female ovaries produce ova. The fusion of male gamete and female gamete to form a zygote is
called fertilisation. There are two types of fertilisation. External and internal and internal fertilisation Example in amphibians takes place in water. The male mounts the female and shed sperms on the eggs are released to increase the chances of
survival. Internal fertilisation This occurs in reptiles, birds and mammals. Fertilisation occurs within the body of the female reproduction system The female reproduction system The female reproduction system.
consist of the following: Ovaries Are two oval cream coloured structures found in lower abdomen below the widucts. They produce the ova produce the oval cream coloured structures found in the lower abdomen
The embryo develops inside the uterus. The inner lining endometrium supplies nutrients to embryo. The embryo is implanted into the inner uterine wall- the embryo. The thick muscles of the uterus from the vagina. It forms the opening to the
 uterus Vagina Is a tube that opens to the outside and it acts as the copulatory and birth canal through the vulva. Structure of male reproductive system The male reproductive system consists of the following: Testis: Each testis is a mass of numerous coiled tubes called semniferous tubules. Each is enclosed within a scrotal sac that suspends them
 between the thighs. This ensures that sperms are maintained at a temperature lower than that of the main body. Seminiferous tubules consists of actively dividing cells which produce the male hormones called androgens e.g.
testosterone. The seminiferous tubules unite to form the epididymis, which is a coiled tube where sperms are carried from testis to urethra. Seminal vesicle produces an alkaline secretion which nourishes the spermatozoa. Prostate gland Produces an alkaline
 secretion to neutralise vaginal fluids. Cowpers' gland Secretes an alkaline fluid. All these fluids together with spermatozoa form semen. Urethra Is a long tube through which the semen is conducted during copulation. It also removes urine from the bladder. Penis Is an intro-mittent organ which is inserted into the vagina during copulation.
Fertilisation in Animals Fertilisation is preceded by copulation in which the erect penis is inserted into the vagina. This leads to ejaculation of semen. The sperms swim through the female's genital tract to the upper part of the oviduct. The head of the sperm penetrates the egg after the acrosome_releases lytic enzymes dissolve the egg membrane
The tail is left behind. Sperm nucleus fuses with that of the ovum and a zygote is formed. A fertilisation membrane forms around the zygote begins to divide mitotically as it moves towards the uterus. It becomes embedded in the wall of the uterus a
process called implantation. By this time the zygote is a hollow ball of cells called blastocyst or embryo. The outermost membrane is the
 chorion which forms the finger-like projections (chorionic villi) which supply nutrients to the embryo forming a fluid filled cavity within which the embryo forming a fluid filled cavity within which the embryo forming a fluid filled cavity within which the embryo lies. Amniotic cavity is filled with amniotic fluid. This fluid acts as a shock absorber and protects the foetus against mechanical injury. It also regutates
temperature. The chorionic villi, allantois together with the endometrium from the placenta by a tube called umbilical cord which has umbilical vein and artery. The umbilical cord increase in
 length as the embryo develops. Role of placenta Protection Maternal blood do not mix. This ensures that the pathogens and toxins from maternal antibodies to pass into the foetus, providing the foetus, providing the foetus with immunity. Nutrition The placenta allows maternal antibodies to pass into the foetus with immunity.
from maternal blood to foetus. Excretion Placenta facilitates the removal of nitrogenous wastes from the foetal blood diffuse into maternal blood. Production of hormones Placenta produces progesterone and
 oestrogen. Gestation period The period between conception and birth is called gestation. In humans gestation takes nine months (40 weeks). The embryo differentiates into tissues and organs during this period. Week 1 to 3: Zygote divides to form blastocyst. Implantation takes place. The three germ layers form endoderm, mesoderm and ectoderm
Nervous system starts to form. Week 4 to 7: Development of circulating and digestive systems. Further development of nervous system, formation of sensory organs, All major internal organs are development of circulating and digestive systems. Further development of nervous system, formation of sensory organs, All major internal organs are development of nervous system, formation of sensory organs. Hair, finger and toe nails grow. Foetus move and
eyelids open. Week 25-30: The fully developed foetus responds to touch and noises and moves vigorously. The head turns and faces downwards ready for birth. Week 31-40: Foetus increases in size. Birth occurs. Reproductive Hormones Secondary Sexual Characteristics Male Testerone is the main androgen that stimulates the development of
secondary sexual characteristics. Broadening of the shoulders. Deepening of the voice due to enlargement of larynx. Hair at the pubic area, armpit and chin regions. Penis and testis enlarge and produce sperms. Body becomes more masculine. Female Enlargement of mammary glands. Hair grows around pubic and armpit regions. Widening of the
hips. Ovaries mature and start producing ova. Menstruation starts. Oestrogen triggers the onset of secondary sexual characteristics. Sexually transmitted infections (STI) Menstruation starts. Oestrogen triggers the onset of secondary sexual characteristics. Sexually transmitted infections (STI) Menstruation starts.
 when the level of progesterone falls and the girl starts to menstruate. The follicle stimulating hormone (FSH) causes the mature ovum to be released from the
Graafian follicle - a process called ovulation. After ovulation progesterone hormone (FS.H) which causes the Graafian follicle to develop in the ovary. It also stimulates the ovary tissues to secrete oestrogen. Oestrogen brings about
 the repair and healing of the inner lining of the inner lining of the inner lining of the uterus (endometrium) which had been destroyed during menstruation. Oestrogen level stimulates the pituitary gland to produce (Luteinising Hormone (L.H). This hormone makes the mature Graafian follicle to release the ovum into the funnel of oviduct, a process called ovulation. After releasing the
ovum, the Graafian follicle changes into a yellow body called corpus luteum. The luteinising hormone stimulates the corpus luteum to secrete a hormone called progesterone which stimulates the thickening and vascularisation of endometrium. This prepares the uterine wall for implantation of the blastocyst. If fertilisation takes place, the level of
progesterone increases and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle. If fertilisation does not occur, the corpus luteum disintegrates and thus inhibits FSH from stimulating the maturation of another Graafian follicle.
 the offspring without variation. New individuals produced asexually mature faster. Process does not depend on external factors which may fail such as pollination. New individuals produced asexually mature faster. Process does not depend on external factors which may fail such as pollination. New individuals produced asexually mature faster.
of offspring. Takes a shorter time and leads to rapid colonization. Disadvantages of asexual reproduction New offspring may be unable to withstand changing environmental conditions. Faster maturity can cause overcrowding and stiff competition. Reduced strength and vigour of successive
generations. Advantages of sexual reproduction Leads to variations which are desirable often show hybrid vigour. High adaptability of individuals to changing environmental conditions. Variations provide a basis for evolutionary changes of sexual reproduction Fusion is difficult if two individuals are isolated. Some variations
 may have undesirable qualities. Population growth is slow. Practical Activities Examining the stages of mitosis About 2 mm of a root tip macerated using a scapel. A cover slip is added and observations made. Different stages of mitosis can be
 observed. Examining the stages of meiosis An unopened bud of Tradescantia is obtained The anther is removed and placed on a microscope slide. A few drops of hydrochloric acid and acetic-orcein stain are added. A cover slip gives a thin squash, which is observed under the microscope. Different stages
of meiosis are observed. To observe the structure of Rhizopus Rhizopus grow on moist bread left under suitable temperature A piece of moist bread is placed on a petri¬-dish or enclosed in a plastic bag and observe daily for four days. Under a low power microscope the sporangia and stolons can be observed. To examine spores on sori of ferns Obtain
 the fern plant. Detach a frond from the plant and observe the under-side using a hand lens to see the raised brown patches - the sori. Open up the sorus to observe the sporangia. Examine insect and wind pollinated flowers e.g. crotalaria, hibiscus/Ipomea, Solanum, incunum. Note the scent, colour and nectar guides. A
 description of the calyx, corolla, androecium and gynoecium is made. Obtain a wmd pollinated flower e.g,' maize, star-grass, sugar-cane, Kikuyu grass. Observe the glumes, spikes and spikelet. Examine a single floret, and identify the androecium and gynoecium. Classifying fruits Obtain different fruits - oranges, maize, castor oil, bean pod
black jack . Observe the fruits, classify them into succulent, dry-dehiscent or indehiscent or indehiscent or indehiscent. Dissection of Fruits Obtain an orange and a mango fruit. Make a transverse section. Observe the cut surface and draw and label the parts. Note that the fruit is differentiated into epicarp, mesocarp and endocarp. Obtain a pod of a legume. Open up the pod and
observe the exposed surface. Draw and label the parts. Note that the fruit wall is not differentiated. Dispersal of fruits and seeds Obtain animal dispersal by animals. Obtain wind dispersed fruit/seed e.g. Nandi flame, Jacaranda Sonchus
cotton seed, Tecoma. GROWTH AND DEVELOPMENT Concept of Growth and Development Growth is a characteristic feature of all living organisms with many cells. This involves multiplication of cells through the process of cell division. This
quantitative permanent increase in size of an organism is referred to as growth. For growth to take place the following aspects occur Cells of organisms assimilate nutrients hence increase in the volume and size of the
 organism. It is therefore possible to measure growth using such parameters as mass, volume, length, height, surface area. On the other hand development is the qualitative aspect of growth which involves differentiation of cells and formations. It is
not possible to measure ac aspects of development quantitative. Therefore development of leaves, flowers and roots. A mature human being has millions of cells in the body yet he or she started from; single cell, that is, a fertilised egg. During sexual reproduction mammals in the body yet he or she started from; single cell, that is, a fertilised egg. During sexual reproduction mammals in the body yet he or she started from; single cell, that is, a fertilised egg. During sexual reproduction mammals in the body yet he or she started from; single cell, that is, a fertilised egg. During sexual reproduction mammals in the body yet he or she started from; single cell, that is, a fertilised egg. During sexual reproduction mammals in the body yet he or she started from the body yet he or she she she she she she she she she sh
 an ovum fuses with a sperm form a zygote. The zygote divides rapidly without increasing in size, first into 2, 4, 8, 16,32, 64 and so on, till it forms a mass cells called morula. These first cell division is called cleavages. The morula develops a hollow part, resulting into a structure known as a blastula (blastocyst). Later, blastocyst cells differentiate into
an inner layer (endoderm) and the outer layer (ectoderm). The two-layered embryo implants into the uterine wall and, by obtaining nutrients from the maternal blood, starts to grow and develops, changes occur in cell sizes
and cell -types. Such changes are referred to as growth and development respectively. These processes lead to morphological and physiological changes in the development process continues the
cells begin to differentiate and become specialised into different tissues to perform different functions. Growth involves the synthesis of new material and protoplasm. This requires a continuous supply of food, oxygen, water, warmth and means of removing waste products. In animals, growth takes place all over the body but the rates differ in the
 various parts of the body and at different times. In plants however, growth and cell division mostly take place at the root tip just behind the root tap just behind the ro
 increase in width (girth) by the activity of cambium cells. The increase in girth is termed as secondary growth. Study Question 1-State two major differences between growth and development Measurement of growth can be estimated by measuring some aspect of the organism such as height, weight, volume and length over a specified period
of time. The measurements so obtained if plotted against time result into a growth curve. Study Question 2 The following results were obtained from a study of germination and early growth of maize. The grains were sown in soil in a greenhouse and at two-day intervals. Samples were taken, oven dried and weighed. See table . Plot a graph of dry
mass of embryo against time after sowing. Describe the shape of the graph. For most organisms when the measurements are plotted they give an S-shaped graph called a sigmoid curve such as in figure . Fig. 4.2: TSie sigmoid growth curve This pattern is due to the fact that growth tends to be slow at first and then speeds up and finally slows down as
 adult size is reached. A sigmoid curve may therefore be divided into four parts. Lag phase (slow growth) This is the initial phase during which little growth occurs. The growth rate is slow due to various factors namely: (i) The number of cells dividing are few. (ii) The cells have not yet adjusted to the surrounding environmental factors. Exponential
 phase (log phase) This is the second phase during which growth is rapid or proceeds exponentially. During this phase the rate of growth is at its maximum and at any point, the rate of growth is due to: (i) An increase in number of cells
 dividing, 2-4-8-16-32-64 following a geometric progression, (ii) Cells having adjusted to the new environment, (iii) Food and other factors are not limiting hence cells are not competing for resources, (iv) The rate of cell death. Decelerating Phase This is the third phase during which time growth becomes
 limited as a result of the effect of some internal or external factors, or the interaction of both. The slow growth is due to: (i) The fact that most cells are fully differentiated. (ii) Fewer ceils still dividing, (iii) Environmental factors (external and internal) such as: shortage of oxygen and nutrients due to high demand by the increased number of cells.
 space is limited due to high number of cells. accumulation of metabolic waste products inhibits growth has ceased and the parameters under consideration remain constant. This is due to the factorial growth has ceased and the parameters under consideration remain constant. This is due to the factorial growth has ceased and the parameters under consideration of metabolic waste products inhibits growth has ceased and the parameters under consideration remain constant.
 that: The rate of cell division equals the rate of cells and tissues are fully differentiated, therefore there is no further increase in the nature of the parameter, the species and the interns! factors. In some cases, the curve continue to increase
 slightly until organism dies as is the case monocotyledonous plants, man invertebrates, fish and certain reptiles. indicates positive growth rate. This negative pattern characteristic of many mammals including
humans and is a sign of physical senesee associated with increasing age. Study Question 3 What happens during the following; log and stationary phases of growth? However, the sigmoid curve does not to all organisms, for example, arthropods. I insects, growth takes place at intervals-volume changes are plotted against time., different curve is
 obtained. This is cal intermittent growth curve. See figure 43, The intermittent growth in insects is due to the fact that they have an exoskeleton and hence growth is possible only when it is shed. This shedding process is known as moulting or ecdysis. However, cell division continues to take place during the inter-moult phase but the expansion of
 tissues is limited by the unshed exoskeleton. Practical Activity I: Project To measure the growth of a plant Requirements Small plots/boxes, meter rule and seeds of beans (or green grams, peas, maize), Procedure Place some soil in the box or prepare a small plot outside the laboratory. Plant some seeds in the box and place it in a suitable place outside
the laboratory (or plant the seeds in your plot). Water the seeds daily. Observe the box/plot daily and note the soil level up to the shoot. Repeat this with four other seedlings. Work out the average height of the shoots for this day. Repeat procedure 5 every
three days for at least three weeks. Record the results in a table form. On the same seedlings measure the length of the leaves and record in the table. Plot a graph of the height of the shoot against time. On the same axes plot length
of leaf against time. Compare the two graphs drawn. Growth and Development in Plants The main growth and development phase in plants begins with the germination of the mature seed. Seeds are of two kinds depending on the number of cotyledons or embryo leaves. Practical Activity 2 To investigate structural differences between
 monocotyledonous and dicotyledonous seeds - Time in days Fig. 4.3: Growth curve showing increase in length of the short homed grasshopper Requirements Bean seeds and maize grains which have been soaked overnight. Scalpel or razor blades, iodine solution, Petri-dish and hand lens. Procedure Using a scalpel or razor blade make longitudinal
 sections (LS) of both the bean seed and the maize grain. Observe the LS of each specimens using a hand lens. Note any structural difference between the specimens using a hand lens. Note any structural difference between the specimens using a hand lens. Note any structural difference between the specimens using a hand lens.
 specimens. On your diagrams indicate the distribution of the stain. Account for the difference in distribution of the colouration with iodine in the two specimens. Structure of the Seed A typical seed coat enclosing an embryo. The seed coat is the outer covering which, in most seeds, is made up of the two layers, an outer testa and
 inner one, the tegmen. The testa is thick; the tegmen is a transparent membrane tissue. The two layers protect the seed bacteria, fungi and other organisms whk may damage it. There is a scar called hilurn on one part of the seed bacteria, fungi and other organisms whk may damage it. There is a scar called hilurn on one part of the seed bacteria, fungi and other organisms whk may damage it.
micropyle. This allows water and air into the embryonic root). The of the radicle (the embryonic sot) are leaved on two seeds the cotyledons, a plumule (embryonic sot). The of the radicle is opposite the micropyle. In some seeds the cotyledons swollen as they contain stored food for growing plumule and radicle. Such seeds, called non-
 endospermic seeds. In ot cases, the seeds have their food stored in: endosperm. Such seeds are call endospermic seeds. Seeds with one cotyledonous. This is the major basis i differentiation between the two large cb of plants, the monocotyledonae aa dicotyledonae
Dormancy in Seeds The embiyo of a dry, fully developed seed usually passes through a period of dormancy. Even if all the favourable environmental conditions for germination are provided to the seed
during this period of dormancy, the seed will not germinate. This is due to the fact that the seed embryo may need to undergo further development before germinate immediately after being shed from the parent plant (e.g. most tropical plants) while others must pass through dormancy period, lasting for weeks, months
or even years before the seed can germinate. Dormancy provides the seeds with enough time for dispersal so that they can germinate in a suitable environmental conditions without depleting their food reserves. The embryo has time to develop until favourable conditions are available e.g.
availability of water. Factors that Cause Dormancy Embryo may not yet be fully developed. Presence of chemical inhibitors that inhibit germination in seeds e.g. gibberellins and enzymes reduces the ability of seeds to germinate. Hard and impermeable seed coats prevent entry of air and water in
 some seeds e.g. wattle. In some seeds the absence of certain wavelengths of light make them remain dormant. Ways of Breaking Dormancy When the seed embryos are mature then the seed embryos can break dormancy and
 needed before seeds with hard impermeable seed coats can germinate. This is achieved naturally by saprophytic bacteria and fungi or by passing through the gut of animals. In agriculture the seed develops into a seedling is
 known as germination. It refers to all the changes that take place when a seed becomes a seedling. At the beginning of germination water is absorbed into the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed through the micropyle in a process known as imbibition and causes the seed to swell.
 and break down the food substances stored in the cotyledons. The radicle grows into a shoot while grows into a shoot whil
 destroyed by unfavourable conditions such as excessive heat, cold or animals. Seeds need certain conditions to germinate and grow. Some of these conditions are external, for example water, oxygen and suitable temperature while others are internal such as enzymes, hormones and viability of the seeds themselves. Water A non-germinating seed
 region of the radical and plumule. Besides, water softens the seed coat which can subsequently burst and facilitate the emergy for cell division and growth. This energy is obtained from the oxidation of food substances stored in the seed through respiration thus making oxygen an important
 factor in seed germination. Seed in water logged soil or seed buried deep into the soil will not germinate below 0°C or above 47°C. The optimum temperature for seeds to germinate is 30°C. At higher temperature the
 protoplasm is killed and the enzymes in the seed are denatured. At very low temperature sthe enzymes become inactive. Therefore, the protoplasm and the enzymes work best within the optimum. This varies from plant to plant. Enzymes Enzymes play
a vital role during germination in the breakdown and subsequent oxidation of food. Food is stored in seeds in form of carbohydrates, fats and proteins which are in insoluble form. The insoluble form by the enzymes. Carbohydrates are broken down into glucose by the diastase enzyme, fats into fatty acids and glycerol by
 lipase, and proteins into amino acids by protease. Enzymes are also necessary for the conversion of hydrolysed products to new plant tissues. Hormones Several hormones play a vital role in germination since they act as growth stimulators. These include gibberellins and cytokinins. These hormones also counteract the effect of germination inhibitors
 Viability Only seeds whose embryos are alive and healthy will be able to germinate and grow. Seeds stored for long periods usually lose their viability due to depletion of their embryo by pests and diseases. Study Question 4 In an experiment to investigate the effect of neat on germination of seeds, ten bags each
 containing 60 pea seeds were placed in a water-bath maintained at 85°C. After every two minutes a bag was removed and seeds contained in it planted. The number that germinated was recorded. The procedure used for pea seeds was repeated for wattle seeds. The results obtained were as shown in the table 4,2, (a) Using a suitable scale and on the
 same axes, draw graphs of time in hot water against number of seeds that germinated for each plant. Use horizontal axis for time and the vertical axis for time axis for time axis for time axis for the vertical axis for time axi
 exposure to heat. Practical Activity 3 To investigate conditions necessary for seed germination Requirements Cotton wool, seeds, water, six fiat bottomed flasks, 2 corks, 2 test-tubes, blotting paper, incubator, refrigerator, thermometer, pyrogallic acid and sodium hydroxide. Procedure> Prepare three set-ups as shown in figure 4.5. Leave the set-ups
to stand for five days. Record all the observable changes that have taken place in the flasks hi each set-up? Types of Germination The nature of germination to stand for five days. Record all the observable changes that have taken place in the flasks hi each set-up? Types of Germination The nature of germination as shown Study Question 5 Which condition was being investigated in set-up? Types of Germination The nature of germination
varies in different seeds. During germination the cotyledons may be brought above the soil surface. This type of germination is known as hypogeal. Set up 1 Set up 2 Set ups Fig. 4.5: Set-up for investigating conditions necessary for
 germination Epigeal Germination During the germination of a bean seed, the radicle grows out through the micropyle. It grows downwards into the soil as a primary root from which other roots arise. The part of the embryo between the cotyledon and the radicle is called the hypocotyl. This part curves and pushes upwards through the soil protecting
 the delicate shoot tip. The hypocotyls then straightens and elongates carrying with it the two cotyledons which turn green and leafy. They start manufacturing food for the growing seedling. The plumule which is lying between two cotyledons, begins to grow into first foliage leaves which start manufacturing food. Hyopgeal Germination In maize, the
 endosperm provides food to the embryo which begins to grow. The radicle along with a protective covering(c(?/eorfci2a) grows out of the plumule grows out of the embryo between the cotyledon and the plumule. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed. The epicotyl elongates and the plumule grows out of the seed.
produce its own food and the endosperm soon shrivels. This type of germination in which the cotyledon remains below the ground is known as hypogeal germination. Practical Activity 4 To investigate epigeal amounts of soil into two
containers labelled A and B. In A, plant a few maize grains. In B, plant a few bean seeds. Water the seeds and continue watering daily until they germinate. Place your set-ups on the laboratory bench. Observe daily for germination. On the first day the seedlings emerge from the soil, observe them carefully with regard to the soil level. Carefully uprootted.
one or two seedlings from each set. Observe and draw the seedlings from each set Label the parts and indicate the soil level on your diagram. Tabulate the differences between the two types of germination studied. Primary and
Secondary Growth The region of growth in plants is found in localised areas called meristems as shown A meristem is a group of undifferentiated cells in plants are found at the tips of shoots and roots, in young leaves, at the bases of the inter-nodes, and in
 Fig. 4.7(a) and (b): Longitudinal section of the stom and cork cambium and cork cambium meristems are responsible for secondary
 growth. Primary Growth Primary growth occurs at the tips of roots and shoots due to the activity of apical meristems originate from the embryonic tissues. In this growth there are three distinctive regions, the region of cell division, cell ejpngarion and eel] differentiation. See figure 4.7. The region of cell division is an area of
 actively dividing meristematic cells. These cells have thin cell walls, dense cytoplasm and no vacuoles. In the region of cell elongation, the cells become enlarged to their maximum size by the stretching of their walls. Vacuoles and
 thickened watt cells. The cells also differentiate into tissues specialised for specific functions. Primary growth results into an increase in the length of shoots and roots. Study Question ;: Mgure; 4-S indkate the appearance of cells at different regions at the appearance of cells at different regions.
 overnight) and then the ink marks are examined. When the distance between successive ink marks are measured, it is found that the first few ink marks, especially between the 2nd and 3"1 mark above tip of root have increased significantly. This shows that growth has occurred in the region just behind the tip of the root. The difference between the
 length of each new interval and the initial interval of 2 mm gives the increase in the length of that interval during that period of time. From this the rate of growth in roots Requirements Germinating bean seeds with radicle of about 1cm in
 length, cork, pin, beaker or gas jar, water, Indian ink, blotting paper or filter paper, marker and ruler marked in mm. Procedure Take the germinating been seed, and using a blotting paper or filter paper, marker and ruler marked in mm. Procedure Take the germinating been seed, and using a blotting paper or filter paper, dry the radical taking care not to damage the root. Using a marker and ruler make light ink marks 2mm apart along the length of the root. See figure 4.10(a)
Make a drawing of the marked root. Pin the seedling and examine the ink marks. Measure the distances between the successive ink marks and record. Make a well labelled drawing of the seedling at the end of the experiment
 and compare with the drawing of the. seedling at the start of the experiment. Study Question 7 What part of the radicle has the ink marks moved further apart? Give an explanation for your answers in (a) above. What is the increase in length within each interval? Work out the rate of growth for the root Secondary Growth Secondary growth results in
an increase in width or girth due to activity of the cambium. In secondary growth new tissues are formed by vascular cambium and cork cambium the vascular bundles. The growth in diameter is due to the enlargement of the primary cells. Secondary growth in diameter are no cambium and cork cambium. In secondary growth in diameter is due to the enlargement of the primary cells.
the division of vascular cambium to produce new cambium to produce new cambium cells between the vascular bundles. This forms a continuous cambium ring. These cambium ring to become meristematic. The new cells produced to the outer side of cambium differentiate to become
 secondary phloem and those to the inner side differentiate to become the secondary xylem. More secondary xylem is formed than secondary phloem. The interfascuiar cambium a/so cuts or Tparenchymatous cells which form secondary phloem. The interfascuiar cambium a/so cuts or Tparenchymatous cells which form secondary xylem is formed than secondary phloem.
 tissues, pressure is exerted on the outer cells of the stem. This results in stretching and rupturing of the epidermal cells. In order to replace the protective outer layer of the stem. In order to replace the protective outer layer of the stem.
new cells on either side. The cells on the inner side of the cork cambium differentiate into secondary cortex and those produced on the outer side become coated with a waterproof substance called suberin. The cork cells increase in number and become the bark of the stem. This end to secondary cortex and those produced on the outer side become coated with a waterproof substance called suberin. The cork cells increase in number and become the bark of the stem.
prevents loss of water, infection from fungi and damage from insects. The corky bark is also resistant to fire and thus acts as an insulatory layer. The bark is normally impermeable to water and respiratory gases. Periodically the cork cells, instead of being tightly packed, they form a loose mass. This mass is known as Jenticel. The lenticles make it
 possible for Fig. 4.12: Section through a lenticel The rate of secondary growth in a stem varies with seasonal changes. During rainy season, xylem vessels and tracheids are formed In large numbers. These cells are large, have thin walls and the wood has a light texture. In the dry season, the xylem and trancheids formed are few in number. They are
 small, thick-walled and their wood has a dark texture. This leads to the development of two distinctive layers within the secondary xylem formed m a year, called annual rings. See figure 4.13. It is possible to determine the age of a tree by counting the number of annual rings. Furthermore climatic changes of the past years can be inferred from the size
of the ring. Primary phloem Secondary phloem Secondary phloem Cambium ring Medullary ray Pith Primary xylem Cortex Fig. 4.13: Annual rings Cork Role of Growth Hormones in Plants Plant body, and play a very important part in regulating plant growth and development. Most growth
hormones are produced at the tip of a shoot and transported downwards to the root. The root tip produces very small quantities of the hormones are produced at the shoot and root tips. Maximum
influence on growth in plants occurs when auxins are produced simultaneously with other plant hormones e.g. gibberellins. Maximum growth response in stems requires more IAA than tn roots. Auxins are known to have various effects on the growth and development in plants. They stimulate cell division and cell elongation in stems and roots leading
to primary growth. Auxins cause tropic responses, which are growth responses in plants due to external stimuli acting from a given direction. On the other hand IAA stimulates the growth of adventitious roots which develop from the stem rather than the main root. Cuttings can be encouraged to develop roots with the help of IAA. If the cut end of a
stem is dipped into IAA, root sprouting is faster. IAA is also used to induce parthenocarpy. This is the growth of an ovary into a fruit without fertilisation. This is commonly u^ed by horticulturalists to bring about a good crop of fruits particularly pineapples. Auxins are known. to inhibit development of side branches from lateral buds. They therefore
 enhance apical dominance. During secondary growth auxins Play an important role by initiating cell division in the cambium and differentiation of these cambium and differentiation of the cambin and differentiation and differentiation of the cambin and differentiation and diff
 concentration of auxins falls in the plant, it promotes formation of an abscission layer leading to leaf fall. A synthetic auxin, 2,4-dichlorophenoxyacetic acid (2,4-D) induces distorted growth and excessive respiration leading to death of the plant. Hence it can be used as a selective weed killer. Gibberellins are another important group of plant growth
 hormone. Gibberellins are a mixture of compounds and have a very high effect on growth. The most important in growth is gibberellins are distinguished from auxins by their stimulation of rapid cell division and cell elongation in dwarf varieties of certain plants. Dwarf conditions are thought to be caused by a shortage of gibberellins
due to a genetic deficiency. Gibberellins are important in fruit formation. They induce the growth of ovaries into fruits after fertilisation. They also induce parthenocarpy. Gibberellins are important in fruit formation of side branches from lateral buds and breaks dormancy in buds. This is common in species of temperate plants whose buds become dormant in
 winter. In addition, this hormone also inhibits sprouting of adventitious roots from stem cuttings, it retards formation of abscission layer hence reduces leaf fall. Gibberellins also break seed dormancy by activating the enzymes involved in the breakdown of food substances during germination. Cytokanins also known as kinetins, are growth substances during the enzymes involved in the breakdown of food substances during germination.
 which promote growth in plants when they interact with auxins. In the presence of auxins, they stimulate cell division thereby bringing about growth of roots, leaves and buds. They also stimulate formation of the callus tissue is used in the repair of wounds in damaged parts of plants. Cytokinins promote flowering and
 breaking of seed dormancy in some plant species. They also promote formation of adventitious roots from stems and stimulate lateral bud development in shoots. When in high concentration cytokinins induce cell enlargement of leaves but in low concentration they encourage leaf senescence and hence leaf fall. Ethylene is a growth substance
produced in plants in gaseous form. Its major effect in plants is that it causes ripening and falling of fruits. This is widely applied in horticultural farms in ripening and harvesting of fruits. It stimulates formation at the cambium meristem
 But it inhibits stem elongation. Ethylene promotes breaking of seed dormancy, inhibits seed germination mostly in pineapples. Abscisic acid is a plant hormone whose effects are inhibits seed germination mostly in pineapples. Abscisic acid is a plant hormone whose effects are inhibits seed germination mostly in pineapples. Abscisic acid is a plant hormone whose effects are inhibits seed germination leading to seed dormancy, inhibits seed germination mostly in pineapples. Abscisic acid is a plant hormone whose effects are inhibits seed germination. In high concentration mostly in pineapples.
 abscisic acid causes closing of the stomata. This effect is important in that it enables plants to reduce water loss. It also promotes flowering. Apical Dominance Although auxins, particularly IAA are important stem and root elongation, they are known to exert
 profound effects on other aspects of plant growth and development. If an apical bud which normally contains high concentrations of auxins is removed, it is observed that more lateral buds lower down the stem sprout producing many branches. This shows that high concentrations of auxins have an inhibitor}' effect on sprouting of lateral buds and
 therefore hinders growth of many branches. This forms the basis of pruning in agriculture where more branches are required for increased harvest particularly on crops like coffee and tea. The failure of lateral buds to develop in the presence of an apical bud is due to the diffusion of auxins from the shoot apex downwards in concentrations higher
 than that promoting lateral bud development. Practical Activity 6 To investigate apical dominance in plants Requirements Tomato seedlings in the tin, leaving the other seedlings growing in a tin. Procedure Cut off the terminal buds intact, Leave the seedlings in the tin, leaving the other seedlings growing in a tin. Procedure Cut off the terminal buds from 3 seedlings growing in the tin, leaving the other seedlings with the terminal buds intact, Leave the seedlings in the tin, leaving the other seedlings growing in a tin. Procedure Cut off the terminal buds intact, Leave the seedlings in the tin, leaving the other seedlings with the terminal buds intact, Leave the seedlings in the tin, leaving the other seedlings in 
Questions 8 list the differences noticed between the two groups of seedlings? Explain how the differences come about. From your observations, explain the basis for pruning tea and coffee. Growth and Development in Animals In higher animals, most cells with the exception of the nerve cells, retain their power of division. Thus, there is a continued
breakdown and replacement of cells. Animal cells undergo rapid cell division and cell differentiation but, unlike plant cells, they undergo very little cell enlargement. In most animals growth immediately after moulting with
periods when no growth increase occurs. This is called discontinuous growth. Insects exhibit two types of reproduction, common in butterflies ai moths. In other insects like the black and t green aphids, the eggs are
 usually product without being fertilised and are able to --- into adult insects. This type of asexual reproduction is referred to; parthenogenesis. Growth and Development in Insects Majority of insects lay eggs that hatch int larvae, which is an immature stage, usual! quite different from the adults in morpholog and behaviour. Depending on the insect
 species a larva is referred to as a grub, maggot or a caterpillar. Generally the larv eats a lot, grows rapidly and sheds its cuticl several times until it reaches full size t< become a pupa. The pupa is an inactive, non feeding stage during which extensivi breakdown and re-organisation of body tissui occur, eventually giving rise to the imago o adult form.
 Such changes, callec metamorphosis, do occur in butterflies moths, bees, wasps and flies. Insects which pass through these stages, namely, egg-larva-pupa, into imago/adult in their development are said to undergo complete metamorphosis. Development in a Housefly (An example of complete metamorphosis) When the egg of a housefly is laid, it
 measures about 1mm in length. The eggs are laid in batches of between 100 to 150. The larvae which hatch from the eggs grow and feed on decaying matter. After this, the larva changes into a pupa encased in a pupal case called die puparium
from which the adult fly later emerges. After emergence, the adult tgkes about two weeks of feeding and growing to attain sexual maturity, i.e. the males can mate and the females are able to lay eggs. Figure 4.14 summarises the life cycle of a housefly. Incomplete Metamorphosis Development in some insects like the locust and cockroaches, involves
 the.egg hatching into a nymph which e!cie!y resembles the adult in every form, except for size and lack of sexual maturity. Pupa case Adult pushes out against the case For such insects to reach the adult, stages, they undergo a series of moults. before fully acquiring the adult size and attaining the sexual maturity. These insects are said to undergo
 incomplete metamorphosis. Development in a Cockroach(An example of incomplete metamorphosis) Cockroaches produce eggs enclosed in moist dark and warm places, for example in cracks of furniture or crevices in walls. It
 takes about a month before the small wingless nymphs emerge. The nymphs feed, and moult about ten times with the total nymphal period lasting about 16 days for all the adult structure to become fully developed. Role of Hormones in Insect Metamorphosis In insects metamorphosis is controlled by hormones. The hormones are produced in three
 glands namely; Neurosecretory cells in the brain ganglia, a pair of corpora allata (singular Corpus allatum) located in the mandibular segment and prothoracic glands in the thorax. During larval cuticle., therefore moulting does not go beyond the larval
 stage. When the larva matures, the corpus allatum disintegrates At this time the neurosecretory cells stimulate the prothoracic glands to produce moulting in insects leading to the laying of the adult cuticle. KCSE Revision Notes Form 1 - Form 4 All Subjects Agriculture Form 1 Notes

Florida Replaces Confederate Soldier Statue of Mary McLeod Bethune to replace their confederate soldier statue. Bethune's is the first state-commissioned statue of a Black person to be included in Statuary Hall Mammalian Circulatory System. Mammals have a closed circulatory system where a powerful heart pumps blood into arteriole divides to form a network of capillaries eventually re-unite to form venules, which form larger vessels called veins. Oct 28, 2021 Now that you know a little bit more about the types and locations of bones, why not test your memory with a bone labeling exercise? Above, you can find an unlabeled diagram ready for you to fill in yourself. Download PDF Worksheet (blank) Download PDF Worksheet (labeled) Password requirements: 6 to 30 characters only (characters found on a standard US keyboard); must contain at least 4 different symbols; Structure of male reproductive system consists of the following: Testis: Each testis is a mass of numerous coiled tubes called semniferous tubules. Each is enclosed within a scrotal sac that suspends them between the thighs. This ensures that sperms are maintained at a temperature lower than that of the main body. Oct 28, 2021 · Cardiovascular system, it's time for a practice test. Here at Kenhub, one method we love using at the beginning of the revision process (after watching a video tutorial, of course!) is labeling structures to train our active recall abilities. Mammalian Circulatory System where a powerful heart pumps blood into arteries divide into smaller vessels called arterioles. Each arteriole divides to form a network of capillaries inside the tissues. The capillaries eventually re-unite to form venules, which form larger vessels called veins. Andrew File System and sharing platform that allowed users to access and distribute stored content. AFS was available at afs.msu.edu and netfiles.msu.edu. AFS was launched in the mid-1990s and was eventually superseded by newer platforms. Expatica is the international community's online home away from home. A must-read for English-speaking expatriates and internationals across Europe, Expatica provides a tailored local news service and essential information on living, working, and moving to your country of choice. With in-depth features, Expatica brings the international community closer together. There is a printable worksheet available for download here so you can take the quiz with pen and paper. Your Skills & Rank. Total Points. 0. Get started! Today's Rank-0. ... Female Reproductive System Labeling 15p Image Quiz. Components of the ... Structure of male reproductive system consists of the following: Testis: Each testis is a mass of numerous coiled tubes called semniferous tubules. Each is enclosed within a scrotal sac that suspends them between the thighs. This ensures that sperms are maintained at a temperature lower than that of the main body. Ensure you request for assistant if you can't find the section. When you are depending on the details you give such as subject area, number of pages, urgency, and academic level. After filling out the order form, you fill in the sign up details. diff -git a/.gitattributes b/.gitattributes b/.gitattributes b/.gitattributes password requirements: 6 to 30 characters long; ASCII characters only (characters found on a standard US keyboard); must contain at least 4 different symbols; 2 days ago · Meiosis questions answer key Urinary and Reproductive Systems (Urogenital) 1. Locate the kidneys; which are bean shaped structures lying toward the back of the abdomen. 2. The ureters are tubes carry urine to the urinary bladder. To find these, you may need to wiggle the kidneys. 3. The urinary bladder is located between the umbilical vessels and stores urine. 4. Welcome to BBC Earth, a place to explore the natural world through awe-inspiring documentaries, podcasts, stories and more. Andrew File System and sharing platform that allowed users to access and distribute stored content. AFS was available at afs.msu.edu and netfiles.msu.edu and netfiles.msu.edu
